#### **NAME**

pow, powf, powl – power functions

### **SYNOPSIS**

```
#include <math.h>
```

```
double pow(double x, double y);
float powf(float x, float y);
long double powl(long double x, long double y);
```

Link with -lm.

Feature Test Macro Requirements for glibc (see feature\_test\_macros(7)):

```
powf(), powl():
```

```
_ISOC99_SOURCE || _POSIX_C_SOURCE >= 200112L || /* Since glibc 2.19: */ _DE-FAULT_SOURCE || /* Glibc versions <= 2.19: */ _BSD_SOURCE || _SVID_SOURCE
```

#### DESCRIPTION

These functions return the value of x raised to the power of y.

#### **RETURN VALUE**

On success, these functions return the value of x to the power of y.

If x is a finite value less than 0, and y is a finite noninteger, a domain error occurs, and a NaN is returned.

If the result overflows, a range error occurs, and the functions return HUGE\_VAL, HUGE\_VALF, or HUGE\_VALL, respectively, with the mathematically correct sign.

If result underflows, and is not representable, a range error occurs, and 0.0 is returned.

Except as specified below, if x or y is a NaN, the result is a NaN.

If x is +1, the result is 1.0 (even if y is a NaN).

If y is 0, the result is 1.0 (even if x is a NaN).

If x is +0 (-0), and y is an odd integer greater than 0, the result is +0 (-0).

If x is 0, and y greater than 0 and not an odd integer, the result is +0.

If x is -1, and y is positive infinity or negative infinity, the result is 1.0.

If the absolute value of x is less than 1, and y is negative infinity, the result is positive infinity.

If the absolute value of x is greater than 1, and y is negative infinity, the result is +0.

If the absolute value of x is less than 1, and y is positive infinity, the result is  $\pm 0$ .

If the absolute value of x is greater than 1, and y is positive infinity, the result is positive infinity.

If x is negative infinity, and y is an odd integer less than 0, the result is -0.

If x is negative infinity, and y less than 0 and not an odd integer, the result is  $\pm 0$ .

If x is negative infinity, and y is an odd integer greater than 0, the result is negative infinity.

If x is negative infinity, and y greater than 0 and not an odd integer, the result is positive infinity.

If x is positive infinity, and y less than 0, the result is +0.

If x is positive infinity, and y greater than 0, the result is positive infinity.

If x is +0 or -0, and y is an odd integer less than 0, a pole error occurs and **HUGE\_VAL**, **HUGE\_VALF**, or **HUGE\_VALL**, is returned, with the same sign as x.

If x is +0 or -0, and y is less than 0 and not an odd integer, a pole error occurs and +HUGE\_VAL, +HUGE\_VALF, or +HUGE\_VALL, is returned.

#### **ERRORS**

See math\_error(7) for information on how to determine whether an error has occurred when calling these functions.

2017-09-15

The following errors can occur:

Domain error: x is negative, and y is a finite noninteger

errno is set to EDOM. An invalid floating-point exception (FE\_INVALID) is raised.

Pole error: x is zero, and y is negative

*errno* is set to **ERANGE** (but see BUGS). A divide-by-zero floating-point exception (**FE\_DI-VBYZERO**) is raised.

Range error: the result overflows

errno is set to ERANGE. An overflow floating-point exception (FE\_OVERFLOW) is raised.

Range error: the result underflows

errno is set to ERANGE. An underflow floating-point exception (FE\_UNDERFLOW) is raised.

#### **ATTRIBUTES**

For an explanation of the terms used in this section, see attributes(7).

Interface	Attribute	Value
pow(), powf(), powl()	Thread safety	MT-Safe

## **CONFORMING TO**

C99, POSIX.1-2001, POSIX.1-2008.

The variant returning *double* also conforms to SVr4, 4.3BSD, C89.

#### **BUGS**

On 64-bits, **pow**() may be more than 10,000 times slower for some (rare) inputs than for other nearby inputs. This affects only **pow**(), and not **powf**() nor **powl**().

In glibc 2.9 and earlier, when a pole error occurs, *errno* is set to **EDOM** instead of the POSIX-mandated **ERANGE**. Since version 2.10, glibc does the right thing.

If x is negative, then large negative or positive y values yield a NaN as the function result, with *errno* set to **EDOM**, and an invalid (**FE\_INVALID**) floating-point exception. For example, with **pow**(), one sees this behavior when the absolute value of y is greater than about 9.223373e18.

In version 2.3.2 and earlier, when an overflow or underflow error occurs, glibc's **pow**() generates a bogus invalid floating-point exception (**FE\_INVALID**) in addition to the overflow or underflow exception.
